Rok: 2016

1 Introduction

Prediction of economic development is very important for every country, not only it is an indicator but also a signal for investors and prosperity. Over time, the estimations are becoming more sophisticated and they are based on serious data supported by statistical methods. Plenty of methods are used for economic evaluation – for example Analytic Hierarchy Process (see [1]), panel regression [2], cluster analysis [3], ARMA-GARCH model according to [4], nonparametric transfer function models as [5] or fuzzy rule-based systems, agent-based models, and non-linear dynamic systems [6]. A linear trend analysis is used as one of the options to describe a future trend, as it reflects dynamics of variables over time. This analysis is not only used in economic field but also in other sciences (for example environmental one, see [7], [8] or medical one [9]).

One country and two methods have been selected for the purposes of this article. As regards a country, a rather untypical economy, but one of the most prosperous countries of the world, Papua New Guinea (PNG hereinafter) has been chosen. As far as the methods are concerned, namely the method of linear trend analysis and the “bottom-up” approach, which is a forecast by country authorities used in economic database, have been chosen. The methods for our researches have not been selected randomly - the second method is used by the International Monetary Fund (IMF) in the World Economic Outlook database (WEO). According to [10] the IMF’s, a “bottom-up” approach means that country teams within the IMF generate projections for individual countries. These are then aggregated, and through a series of iterations, where the aggregates feed back into individual countries’ forecasts, the forecasts converge to the projections reported in the WEO. As the forecasts are made by the individual country teams, the methodology varies from country to country and series to series, depending on many factors.

According to IMF staff, poor data situation does not allow analysts to apply any formal economic model to the PNG economy. So they (staff) rely on both qualitative and quantitative information in forecasting macroeconomic indicators, visiting the country and interviewing officials, bankers and researchers.

The first method has been chosen due to its clarity and possibility of comparison with the second method. The data used for linear trend analysis and description of the economic situation of PNG have been drawn from the statistics of the World Bank [11]-[14], Asian Development bank [15], [16] Bank of Papua New Guinea [17], the International Monetary

Fund [18] and UNCTAD [19]-[21], regarding the fact that the analyses must be conducted on specific data.

A prediction of five macroeconomic indicators was developed and applied, including GDP, GDP growth, inflation, current account and budgetary balance as a percentage of gross domestic products in the years 2014-2016.

The aim of the article is to verify the hypothesis that both the methods determine different values of predicted variables. The article is divided into four parts - introduction, initial economic conditions, methodology and conclusion. Introduction is focused on a brief description of the nature of the article, the second part deals with initial conditions and the status of PNG economy in the years 2006-2013 in detail, which is a basis for understanding the future development of this developing Pacific island country. In the following part a linear trend analysis is characterized, calculations of the estimation are made and subsequently compared with “bottom-up” approach. In the part of conclusion the basic findings reached by the authors are summarized and the initial hypothesis is confirmed.

2 Problem Formulation

Papua New Guinea is currently one of the fastest growing economies in the world [22]. According to [23] PNG belatedly and briefly experienced rapid and uneven economic growth during the 1990's, despite not always conception steps of the government in the public sector (according [24] or [25]). Since 2005, PNG has experienced sustained and strong economic growth that has not been seen before, the growth averaged out 5 per cent between 2005 and 2009, despite the global financial crisis [26]. On the other hand the [27] claimed that Papua New Guinea has failed to develop since its independence, resulting in shocking social consequences. However, economic development, [28] as well as labour market reforms [29], are actively undermined by Papua New Guinea natural resources.

However, since the beginning of the reporting period PNG has disposed mainly with trade balance surplus, a low unemployment rate (to 2013 PNG it showed only 2.1% of the unemployed), good fiscal discipline and a high degree of export openness (in case of PNG the growth is led by export – see [30]).

2.1 Internal Economic Situation

The economic growth in Papua New Guinea is one of the fastest in the world nowadays. The concept of the economic development in PNG is supported by government program, the aim of which is to achieve the status of a middle income country by 2030. The primary instrument for achieving this goal is the realization of a project of natural gas liquefaction with a budget of more than USD 15 billion, planned from 2015 onwards. The PNG government involved in the project with less than 20% calculates with the creation of up to 8.000 new jobs and at least doubling GDP [31]. The financial resources obtained in this project will then be invested in improving infrastructure, education and health. As claims [32], financial capital is important in uplifting the socio-economic conditions in the community as it affects the capacity of households to mobilize assets and endure periods of uncertainties. From the perspective of the economic growth, tourism industry appears to be very promising.

Neither the global crisis influenced the positive development of the economic growth of PNG. It caused only a slight decline in GDP in 2009 (see Table 1). The high growth rates of GDP involved the high prices of raw materials and commodities exported from PNG (especially in 2011). For the next few years the growth of GDP is expected to continue, however, it should slow down due to completion of the implementation of the above mentioned project. After its launch, a reverse and a significant increase of GDP is expected due to exports of this commodity. The high inflation rate of the country has been the result of government supporting the large mining projects and high prices of imported commodities since 2008. Although the inflation was reduced in 2012 (see Table 1) due to the fact that the Central Bank of PNG responded by increasing interest rates and mandatory level of bank reserves, in the coming years its decline is expected.

The indicators of the inherent stability of economy include, besides GDP growth and inflation rate development, fiscal discipline as well as the management of public resources. In the period monitored, the government of PNG managed an almost balanced budget (see Table 1) and its ratio of budget balance to GDP can be envied by any developed economy. It is interesting that the funds resulting surpluses are placed in the so called trust funds, which are then used to finance priority spending and investment.

Table 1 Internal Indicators of PNG 2006-2013

Indicators	2006	2007	2008	2009	2010	2011	2012	2013
GDP (mil USD)	5 599,0	6 329,0	8 010,0	7 915,0	9 480,0	12 393,0	15 654,0	15 289,0
GDP growth (%)	2,6	7,2	6,7	5,5	8,0	9,0	8,0	5,4
GDP per capita (USD in PPP)	896,5	989,5	1 223,1	1 180,7	1 382,7	1 844,5	2 168,0	2 539,1
Inflation rate (%)	2,4	0,9	10,8	6,9	6,0	4,4	4,5	5,0
Revenues	6 311,5	7 006,6	7 073,3	6 651,3	8 278,9	9 304,9	9 566,0	9 374,6
Expenditures	5 767,3	6 552,4	7 551,8	6 687,2	8 092,6	9 370,6	10 047,0	11 872,4
Budgetary balance	544,2	454,2	-478,5	-35,9	189,3	-65,7	-480,9	-2 497,8
Budgetary balance % GDP	3,2	2,4	-2,2	-0,2	0,7	-0,2	-1,5	-7,2

2.2 External Economic Situation

Basic indicators of foreign trade were selected to characterize the external economic situation, such as trade balance, export and import, balance of payments (without foreign exchange reserves) and foreign debt. As a major exporter of commodities, Papua New Guinea consistently runs merchandise trade surpluses (see Table 2). Papua New Guinea exports mainly minerals (gold, oil, copper, coffee, cocoa, vegetable oils), which account for 52% of total exports, fish and wood. PNG is primarily dependent on the regular import of food for daily consumption and finished products. The highest value belongs to the import of manufactured goods (51% of total import), where import of building materials is the most evident, associated with the implementation of large investment projects. Other important import commodities are fuel and chemicals. The main trading partner of PNG is Australia, other important partners, particularly import partners are the U.S.A, and Singapore (increased investments and the inflow of materials for implementation of large projects). The second largest export country is Japan, PNG also cooperates with countries of Europe, mostly Germany. Other major partners are China, the Philippines and Malaysia, Hong Kong and Vietnam [33].

The current account balance as a percentage of GDP provides an indication on the level of international competitiveness of a country. Countries recording a strong current account surplus have an economy heavily dependent on exports revenues, with high savings ratings but weak domestic demand. On the other hand, countries recording a current account deficit have strong imports, a low saving rates and high personal consumption rates as a percentage of disposable incomes. Until 2008, PNG showed a positive balance, but in the

post-crisis years the value started to decrease and reach negative numbers (see Table 1). The balance of payments is compiled both for monitoring cross-border flows of goods, services, capital and money, and for providing information to government institutions on the status of the economy in the world and support decision-making on monetary and fiscal policy. The balance of payments must always be balanced, which is an option of reserves items. For purposes of our analysis the payment balance account without the balancing items was used. PNG balance of payments showed a negative value in two years, in 2008 and 2012. In 2008, other investments in the financial account (bank lending to government sector or business loans abroad) were the main reasons for the negative value and in 2012 it was the high current account deficit. The reason for the negative current account balance was a global crisis, when the increasing deficit of the balance of services including tourism, transport or insurance, could not offset the income from international trade in goods. According to the [34], the current account balance will reach positive values in 2015.

Table 2 External Indicators of PNG 2006-2013

Indicators	2006	2007	2008	2009	2010	2011	2012	2013
Merchandise Trade Balance (mil. USD)	2 214,0	2 119,0	2 665,0	1 522,0	2 216,0	2 689,0	1 566,0	487,0
Export growth (%)	27,3	12,4	22,1	-23,1	30,7	20,3	-8,5	-11,5
Import growth (%)	30,7	30,3	19,2	-8,5	23,1	20,5	12,0	7,7
Current Account to GDP (%)	8,0	2,9	9,9	-7,2	-6,5	-1,3	-14,9	-21,5
Current Account (mil. USD)	443,0	185,5	795,6	-586,1	-633,3	-172,6	-2 300,5	-3 307,7

3 Problem Solution

Time series analysis is a comparison of ratio indicators or any variables in time and is used mainly to detect negative trends (orientations) of indicators. In order to use the results of time series analysis to simple economic estimates of future economic development, a suitable form of functional dependence which best describes the revealed trend of the time series evolution must be found. For these reasons we have used statistical methods of regression and correlation relationships with the help of a few, previously identified and recommended functions for monitoring the economic development. One possible description of trends in time series is trend analysis, which belongs to one of the frequently used methods, as it allows a relatively simple estimate of future values of time series and analysis using moving average,

which is used for longer periods of time, because unlike the first method it does not expect constant parameters.

For our analysis, two specific methods were selected and compared, linear trend analysis (hereinafter LTA) and the “bottom-up” approach used to produce individual country forecasts. The methods vary substantially depending on characteristics of each country but they do not differ according to the proposed uses of the forecasts. Country authorities usually used the judgment, macro framework or their own forecasts more than econometric models, vector-autoregression or reduced - form equations. These methods will not be analyzed in detail, we will focus on the description of the first method according to which the below mentioned data were calculated.

The calculation of trend analysis is done using equation:

$$T_t = \frac{\sum y_t}{n} + \left[\left(\frac{\sum y_t * t'}{\sum t'^2} \right) * t \right] \quad (1)$$

where $\frac{\sum y_t}{n} = \beta_0$, $\frac{\sum y_t * t'}{\sum t'^2} = \beta_1$, n is the number of years of examined time series and t is a time coefficient for the predicted year.

Then the equation can be as follows

$$T_t = \beta_0 + \beta_1 * t \quad (2)$$

In the calculation it was necessary to choose a time series y_t , in this case the above mentioned economic indicators, and to determine the period of availability of data of yearly values for the period 1992-2012. Then, for each value of time series in individual year time coefficient t' is given, which takes values $<-t', +t'>$ according to the time series length. This factor is firstly compounded by the square and then multiplied by a time series ($y_t * t'$). After performing these calculations separately for each year, sums of indicators are calculated $\sum y_t$, $\sum t'^2$ and $\sum y_t * t'$. For the calculation of the first necessary coefficient into the equation trend analysis, which is β_0 , we needed to know $\sum y_t$ and the coefficient n . Then it can already be put into the equation $\beta_0 = \sum y_t / n$ and the value of β_0 could be calculated for predicted year. The second coefficient β_1 is a simple proportion of already determined values $\sum y_t * t'$ and $\sum t'^2$. The last unknown in the equation trend analysis is t , which is a time coefficient for the predicted year, which always achieves one higher value than the maximum value $+t'$. Finally, and T_t the resulting value of the trend analysis of time series predicted for the first year. By repeating the procedure, in which already the value of the time series for the preceding

predicted all of the previous values are put into the equation year is subsequently incorporated, the value of the time series for the predicted following year can be calculated. Calculations and results are given in Appendix A to E.

To find the reciprocal independent between set variables, we applied the chi-square test for independence. The significant level is 0.05. For that we state two hypotheses. The null hypothesis (H_0) states that the level of variable 1 (v_1) does not help predict the level of variable 2 (v_2). That is, the variables are independent. The alternative hypothesis (H_1) is that the level of v_1 can help predict the level of v_2 .

H_0 : Variable 1 and variable 2 are independent.

H_1 : Variable 1 and variable 2 are not independent.

If the probability value (p-value) is less than the significance level of 0.05, null hypothesis is rejected, which means that the variables are not independent.

The second test that we made was the t-student test that shows the statistical significance. Even in this case null and alternative hypotheses are determined and tested at a significance level 0.05:

H_0 : Variables v_1 and v_2 are equal to zero.

H_1 : Variables v_1 and v_2 are not equal to zero.

If the probability value (p-value (F)) is less than the significance level of 0.05, null hypothesis is rejected, which means that the variables are statistically significant.

These two tests were used for all indicators by OLS model with 24 number of observation, where dependent variable (v_1) was the predicted variable by LTA, v_2 than predicted variable used by IMF. The results are shown in the Tables 3-7 below.

Table 3 Results of Tested GDP

	<i>Coefficient</i>	<i>Std. Error</i>	<i>t-ratio</i>	<i>p-value</i>

R-squared	0.233539
Adjusted R-squared	0.190957
P-value(F)	0.030885

Source: Author calculations

In all cases, the probability value (p-value) is less than the tested significance level of 0.05, null hypothesis is rejected, which means that the level of v_1 can help predict the level of v_2 .

The values of correlation coefficient, which are shown as R-squared indicates the strength of dependence of selected variables (with exception of current account). Specifically, it means that the predicted values set by LTA are approximately 72-98% dependent on changing of the prediction of IMF – the most in the case of inflation rate, the least in the case of budgetary balance. On the other hand the value of current account by LTA is dependent on the changing of prediction of IMF only in 23%.

Other values shown in the tables are the values of adjusted R-squared – it indicates how much of the total variance of the dependent variable is explained by this model. With exception of last adjusted variable with only 19%, it is more than 70% in all cases.

The level of significance is compared with the p-values(F) in the tables above. Thus, if these values are lower than the level of significance (they are in all cases), the null hypothesis can be rejected and so the alternative hypothesis is valid, therefore, variables are statistically significant.

3.1 Linear Trend Analysis versus “Bottom-up” Approach

For comparison of basic economic indicators (GDP, GDP growth, inflation rate, the state budget balance to GDP and current account) and for verification of the hypothesis, the data of IMF WEO database are used [35]. These data are then compared with our own values calculated by linear trend analysis (LTA) in the years 1993 to 2013, see Appendix A-E.

The calculated values, compared with the “bottom-up” approach, are shown in Table 8. The years 2014-2016 were selected as a predicted period. A longer-term analysis is meaningless because of the processing time series of historical data that do not reflect current economic and political situation in the monitored economies.

Table 8 Prediction of Basic Economic Indicators of PNG by LTA and “Bottom-up” Approach

Indicators	Est.	2014	2015	2016
GDP (mil. USD)	LTA	12 220,0	12 348,0	12 527,0
	IMF	16 096,0	20 328,0	21 085,0
GDP growth (%)	LTA	8,7	8,4	7,2
	IMF	5,8	19,6	3,3
Inflation rate in CPI (%)	LTA	2,6	3,1	3,3
	IMF	5,3	5,0	5,0
Budgetary balance (% GDP)	LTA	-1,0	-0,9	-1,1
	IMF	-7,2	-2,5	-2,1
Current account (mil.USD)	LTA	-1 571,0	-1 616,0	-1 645,0
	IMF	-1 827,0	2 749,0	1 999,0

Source: Author calculations

The first indicator compared in our research was the prediction of future GDP development. Among all of the monitored indicators, there is the biggest difference between the two predictions. While the method LTA calculates with a slight increase – based on historical data, country authorities of IMF WEO database estimates a sharp increase in GDP based on current investments. This fact is also reflected in the estimate of GDP growth – LTA method predicts a steady decline in GDP growth, “bottom-up” approach expects further growth in 2015. As far as inflation rate is concerned, IMF database estimates its stable range around 5%, while trend analysis expects growing inflation rate of between 2-4%.

Divergent results are also obvious in predictions of the budgetary balance to GDP. The prediction by “bottom-up” approach expects a continuation of negative result of this indicator as well as the deficit of general government budget. According to the trend analysis, PNG will achieve almost a balanced state budget balance, as well as its share of GDP. The current account reaches negative values by LTA during the reporting period and the period predicted but forecast by IMF WEO database shows positive results since 2015. A positive trend is that every year the value of exports and imports is increasing and shows a greater involvement of PNG in the international division of labour.

4 Conclusion

Despite of the fact that Papua New Guinea belongs to developing economies of the Pacific region, it has a high rate of economic growth and other economic indicators, which are higher than the development in the world economy. Recent global crisis has affected only PNG's external debt (similarly to other developing economies, see [36]). The economic situation of the country as a base for further estimation was described in the first part of this paper. However, the situation in the future may be different. Though the prospects of PNG economy are very promising, we assessed, whether the results of estimation may vary if we use different statistical methods. The forecast by World Economic Outlook was compared with the method of linear trend analysis LTA. We have chosen five macroeconomic indicators such as gross national product, its growth, as well as budget balance to GDP and current account. These indicators are monitored in 2014-2016. We have set the hypothesis that the two methods used for the determination come to different values of variables and the purpose of the article was to verify the hypothesis.

By comparison of these two methods it was found out that there are differences not only in values, but also in the degree of the difference. LTA method was more pessimistic in predicting GDP and current account but it was optimistic for the following three indicators (GDP growth, inflation rate and budgetary balance). As regards GDP indicator, the validity of trend analysis is the most noticeable. It is based on the fact that GDP has been growing recently, but considering the historical developments it should not reach such high numbers as WEO database expects. While the trend analysis expects a drop compared to 2013, and then a slight increase, the available prediction by WEO database takes into account a potential positive impact of the investment project and mining. PNG would still continue to be one of the fastest growing economies in the world. A possible decline in GDP growth in the predicted period, according to the LTA, is associated with the completion of the construction of natural gas liquefaction project, which would bring a decline in mining of raw materials. After implementation of this project into practice in 2015, GDP growth should increase again.

From the above mentioned it is obvious that the hypothesis was verified - regarding all the measured parameters, the values of the two methods differed. It can be concluded that for predicting the development of PNG, a combination of trend analysis and an appropriate prediction is the right alternative. The conclusions of trend analysis can be considered to be theoretical values, which PNG should reach according to its historical development, while the

prediction according to “bottom-up” approach includes the temporary status and changes, which may be very useful for the exact prediction.

Not only a method based on a linear basis, but also non-linear methods are used for forecasts. We will continue to monitor trends in the economic development of this interesting economy and our future research in this area will be based on application of one of the second mentioned method, and this method of Double Exponential Smoothing. This method is applied for updating of the trend by using non-linear optimization techniques, such as the Marquardt Algorithm.
